1. Introduction

2. Environment Setup for R programming Developers

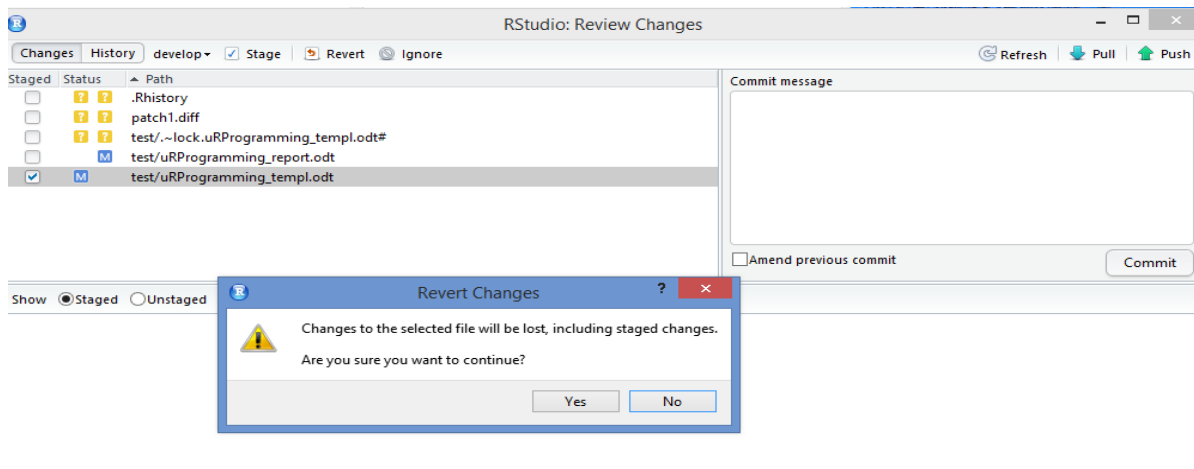

2.1 *Environment setup*

	Package	Version
1	uRProgramming	1.1.1
2	tcltk	3.2.3
3	log4r	0.2
4	odfWeave	0.8.4
5	XML	3.98-1.3
6	lattice	0.20-33
7	chron	2.3-47
8	stats	3.2.3
9	graphics	3.2.3
10	grDevices	3.2.3
11	utils	3.2.3
12	datasets	3.2.3
13	methods	3.2.3
14	base	3.2.3

```
> environment("ls")
usage of ls()
functNameusage of ls(all=TRUE)
functName
> cat("Current Working Dir \n", getwd())
Current Working Dir
C:/Users/zekai/Documents/rstudio_projects/odfWeaveTmp
```

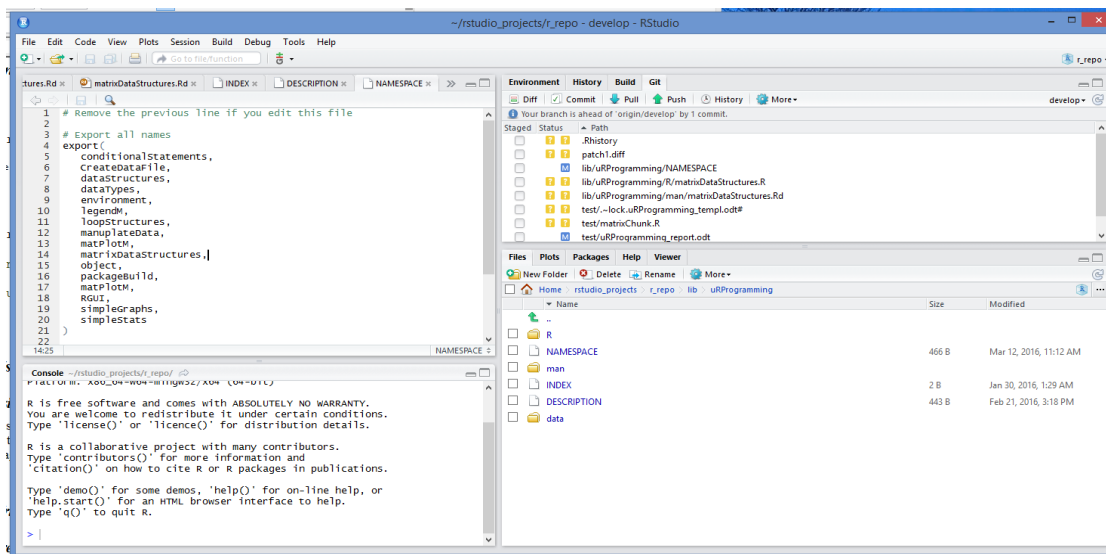

2.2 *Using Version Control System*

Talk about version control system, why we use git system. Briefly explains the benefits of git.

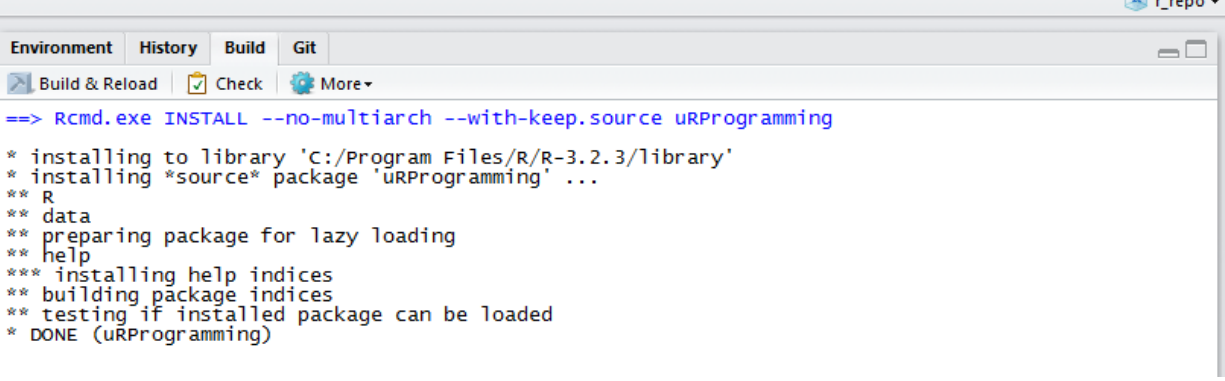

2.3 Using IDE to develop R scripts

Rstudio is our choice of integrated development environment (IDE). It allows to use modern software tools like git version control system. The Rstudio is also integrated with rapid build tools for the packages. Use figures from open office

2.4 Writing Functions

2.5 Create R package System

The screenshot shows the RStudio interface with the console pane active. The console displays the command `Rcmd.exe INSTALL --no-multiarch --with-keep.source uRProgramming` and its output. The output indicates that the package is being installed to the library `'C:/Program Files/R/R-3.2.3/library'`. It lists the steps: installing the source package, installing R, data, and help files, preparing the package for lazy loading, installing help indices, building package indices, testing if the package can be loaded, and finally, `DONE (uRProgramming)`. The RStudio window has tabs for Environment, History, Build, and Git. Below the tabs are buttons for Build & Reload, Check, and More.

```
Environment History Build Git
Build & Reload Check More
==> Rcmd.exe INSTALL --no-multiarch --with-keep.source uRProgramming
* installing to library 'C:/Program Files/R/R-3.2.3/library'
* installing *source* package 'uRProgramming' ...
** R
** data
** preparing package for lazy loading
** help
*** installing help indices
** building package indices
** testing if installed package can be loaded
* DONE (uRProgramming)
```

2.6 *Open Office as an Integrator*

3 . Simple Data Types and Objects

4. Control Structures

Control structures are used to change a flow or follow a logic. The control structures are easily could make any program more followable for maintenance and understanding, they could also turn the most unfollowable code. Control structures are very straight forward when used in a modular way in a less number of statements or calling other reusable functions.

In the following sections, the usage of *if* block will be explained with examples. The samples should help reader to solidify the understanding of the control structures.

4.1 If statements

Let's use simple vector which contains only numbers, check if numbers is equal to specific value assign iFound as True.

If(Statements) { Assignment}

```
x<-c(0,3,6,9,12,15,18,21,24)
if(x[which(x==6)]==6) {iFound<-TRUE}
print(iFound)
```

In the above example, which finds the index number for the value. The usage of *which* in vector is pretty powerful as shown in the example. The *which* statement is pretty handy determining the index of vector or array. When the vector with right index with exact value found, iFound assigned to be *true*.

Logical operators in R are

Operator	Description
==	Equal to
!=	Not equal to
<	Less than
<=	Less or equal to
>	Greater than
>=	Greater or equal to
&	And
	Or

Following code snippet is simple example of how to use logical operators. The first example is the exacty *equal* to operator. The second example demonstrates *less than or equal* to operator and assigning the value based on the result. The third example shows *greater than* comparison. The last example is combination *greater than, and, less then or equal* to.

```
Ex. 1
if(demDat[indx,1] ==1 ) {demDat[indx,1]<- 'M' }
```

Ex.2

```
if(demDat[indx,2] <=25 )demDat[indx,2]<-'Y'
```

Ex.3

```
if(demDat[indx,2] > 50 ) {demDat[indx,2]<-'O'}
```

Ex.4

```
if(demDat[indx,2] > 25 & demDat[indx,2] <=50 )demDat[indx,2]<-'M'
```

4.2 If then Else statements

If then else block is used when comparison expected to result in a choice either true or false. It gives the programmer, the power to control logical flow. In R programming, if then else blocks are in the following format

```
If ( Statements) { Assignment}  
else (statements) { Assignment}
```

4.3 Switch statements

5. Loop Structures

The loop structures are needed to access elements of vectors, matrix, list and data frame. The access of the data is important to reach or manipulate the elements. The *for* and *while* loop are used to iterate elements.

5.1 For loop

The for loop is used for sequentially access the data elements. Each element of data structures can be reached, used or manipulated within the *for* loop. The *for* loop is in the following format.

```
for (values in sequence) {
    statement
}
```

The following code snippets how *for* loop is used. In the following example, 100 number with specified seed assign to vector. This vector has only integers for demonstration purpose.

```
set.seed(312)
#create 100 random number between 0 and 1000
xInt<-floor(runif(100,0,1000))
for(indx in 0:length(xInt) ){
  if(indx %%10 ==0){print(xInt[indx])}
}
numeric(0)
[1] 450
[1] 261
[1] 405
[1] 295
[1] 763
[1] 356
[1] 833
[1] 329
[1] 419
[1] 948
```

5.2 While loop

The access of certain elements could be controlled by using while loop, the expression determines executing statements or not.

```
while(expression){
    statement
}
```

In the following example, the elements between two indices are assigned as either even or odd. Execution will stop when expression is false, otherwise statements within the block is executed.

```
set.seed(312)
```

```
#create 100 random number between 0 and 1000
xInt<-floor(runif(100,0,1000))
index<-80
while(index<=length(xInt)){
  xInt[index]<-ifelse(as.integer(xInt[index]) %%2==0,"Even","Odd")
  if(index %%4 ==0){print(xInt[index])}
  index<-index+1
}
[1] "Odd"
[1] "Even"
[1] "Odd"
[1] "Odd"
[1] "Odd"
[1] "Even"
```

6. Data Structures

The main R structures are either vector (array), matrix, data frame and list. The usage and examples how to use data structures will help reader to access data to manipulate and display.

6.1 Vector

The vector or one dimensional array is extremely useful data structure in R. We can easily store continuous and categorical data in a vector. In general, the iterator method is used to reach elements of vector to manipulate or use. The R has built in methods in *base-package* such as *c*, *which*, *sum*, *append*, *rev* and *sort* are some of the functions. Here, we will explain and the usage of some of the function with vector data structures. The first example shows how to store strings into a vector, use sort function to alphabetically store into the same vector and print out the vector. The second example is creating random number generated vector elements. Select only subset of elements (every 10th element), assign the values to new vector and find the sum of it. The loop structure is also used to demonstrate how to reach elements of the vector.

Ex. 1

Assign a vector with text fields

```
print(xText)
[1] "Elma"      "Portakal" "Armut"     "Erik"      "Seftali"   "Kaysi"
sort the vector and reassign to itself
xText<-sort(XText)
[1] "Armut"     "Elma"      "Erik"      "Kaysi"     "Portakal" "Seftali"
print(xText)
```

Ex. 2

```
set.seed(312)
#create 100 random number between 0 and 1000
xInt<-floor(runif(100,0,1000))
Find the vector elements has modulus of 10
indicies<-which(xInt%%10 ==0)
print(indicies)
[1] 9 10 15 16 22 34 56 81
The usage of for loop is shown previously.
xNewInt<-array('',dim=length(indicies))
xNewInt<-as.numeric(xNewInt)
for(indx in 1:length(indicies) ){
xNewInt[indx]<-xInt[indicies[indx]]
}
sum(xNewInt)
[1] 4310
```

6.2 Matrix

Matrix is two dimensional array. Matrix is used to store rectangular and table data. Any time, one has a data in a spreadsheet, table or regular form of data, the matrix data structure should be one of the choices. In order to reach elements of matrix, the indices of matrix is used.

In following examples will show how to use matrix data structure to reach and manipulate the data. In the first example, we created simple one dimensional array and parse elements and created matrix to print in a table format. In the second example, we read a simple gridded data and reach each of the elements using loop structures for the demonstration purposes. In third same example, some of basic functions like *which*, *colSums*, and *colMeans* from base R library is used.

Ex. 1

```
set.seed(312)
#create 100 random number between 0 and 1000
xInt<-floor(runif(100,0,1000))
colAVals<-as.integer(xInt[1:10])
colBVals<-as.integer(xInt[25:35])
matr<-matrix(c(colAVals,colBVals),nrow=length(colAVals),ncol =
2,dimnames=list(NULL,c("colA","colB")))
return(matr)
```

colA	colB
791	185
661	235
934	678
451	317
819	405
669	751
228	329
426	816
460	870
450	131

Ex. 2

```
data(mtcars)
mpgVals<-array("",dim=dim(mtcars)[1]
for (rowIndx in 2:dim(mtcars)[1]){
for (colIndx in 1:dim(mtcars)[2]){
if(colIndx ==1){mpgVals[rowIndx-1]<-mtcars[rowIndx,2]}
}

print every 4th element
print(mpgVals[seq(1,length(mpgVals),4)])
[1] "6" "6" "6" "8" "4" "8" "4" "6"
matr<-as.matrix(mtcars)
```

The following *mtcars* data from R baseline will be used to demonstrate some of available functions for the matrix data structures.

	mpg	cyl	disp	hp	drat	wt	qsec	vs	am	gear	carb

Volvo 142E	21.40 0	4.000	121.0 00	109.0 00	4.110	2.780	18.60 0	1.000	1.000	4.000	2.000

In the Ex. 3, *which* is allowing us to assign the row to the vector when the rowname of matrix is “Merc 450SE”; see the code snippet with “`matrx[which(rownames(matrx))=="Merc 450SE"),]`”. The *colSums* finds the sum of each columns, there is also *rowSums* which finds the sum of each row. The *colMeans* is average values for each column, the *rowMeans* yields the average values for each row.

Ex. 3

```
data(mtcars)
matrx<-as.matrix(mtcars)
merc<-matrx[ which(rownames(matrx))=="Merc 450SE"),]
print(merc)
colSums(matr)
colMeans(matr)
matr<-rbind(colSums(matrx),colMeans(matrx))
```

6.3 DataFrame

The dataframe is used frequently in R. The dataframe can store different type of data. In the following simple example, 4 vector (ad, soyad, okulNo, ve kayitTarihi) will be stored in dataframe (df). The *str* function will display the structure of dataframe object. The *structure* of dataframe will give further attributes. The summary function give some of statistics for dataframe variables.

```

ad<-c('Ali','Ahmet','Fatma','Ayse')
soyad<-c('Kasap','Berber','Kaya','Gul')
okulNo<-as.integer(c(11,23,5,100))
kayitTarihi<-as.Date(c('1979-11-1','1980-5-4','1979-5-25','1981-10-10'))
df<-data.frame(ad,soyad,okulNo,kayitTarihi)
structure(df)
      ad  soyad okulNo kayitTarihi
1  Ali  Kasap    11  1979-11-01
2 Ahmet Berber    23  1980-05-04
3 Fatma  Kaya     5  1979-05-25
4 Ayse   Gul    100  1981-10-10

```

Dataframe(df) variables can be retrieved by using `df$varName` or `df['varName']`.

6.4 List

The list is a best way to store different type of objects. Once could store array, matrix and dataframe objects to list and retrieve easily. In following simple example, the list (*liste*) stores *x1* vector with sequential data, *y1* vector with random values between 0 and 100, and dataframe *df1* with multiple variables such as *okulNom* and *kayitTarihim*. Access to list variables are straightforward with list name joined by \$ and variable name, or list name and variable name in the double bracket. The following example shows different ways to access the list variable.

```

x1<-seq(10,100,10)
y1<-runif(10,0,100)
okulNom<-as.integer(c(11,23,5,100))
kayitTarihim<-as.Date(c('1979-11-1','1980-5-4','1979-5-25','1981-10-10'))
df1<-data.frame(okulNom,kayitTarihim)
liste<-list(x=x1,y=y1,df=df1)
structure(liste)
$x
[1] 10 20 30 40 50 60 70 80 90 100

$y
[1] 11.36411 86.44317 87.57389 78.09636 20.47147 92.38561 28.94030 33.65846
32.88561 70.89434

$df
      okulNom kayitTarihim
1         11  1979-11-01
2         23  1980-05-04
3          5  1979-05-25
4        100  1981-10-10

liste$df
      okulNom kayitTarihim
1         11  1979-11-01
2         23  1980-05-04
3          5  1979-05-25
4        100  1981-10-10
liste[["x"]]

```

```
[1] 10 20 30 40 50 60 70 80 90 100
```
